

# ReFuelEU Aviation: T&E's recommendations

An overdue first step to reduce aviation's climate impact

---

November 2021

## Context

Aircraft rely exclusively on fossil jet fuel to operate, which explains why growing passenger numbers have rapidly increased emissions from the sector. Carbon pricing and modal shift are important, but it's only when we swap fossil jet fuel for truly sustainable advanced fuels (SAFs) that emissions from flying will fall. Such a switch can address both CO<sub>2</sub> and non-CO<sub>2</sub> effects, but to differing degrees. To date, no effective measures have been put in place at European level to achieve such a switch. The ReFuelEU Regulation proposal changes that.

## What has the European Commission proposed?

The proposal introduces an obligation on jet fuel suppliers to blend a growing share of SAFs (advanced biofuels and e-kerosene) into fuel provided at major airports in the EU. That obligation covering both types of fuels starts in 2025 at 2% and grows to 5% in 2030 and further beyond that.

- The regulation mandates the use of advanced biofuels (both part A and B of the renewable energy directive (RED) Annex IX) and e-kerosene
- ReFuelEU excludes the use of food and feed crop-based biofuels, which have a higher emissions profile than fossil fuel and generate negative impacts on biodiversity and local communities.
- The support for e-kerosene is especially important, as it is the only fuel type which can be sustainably scaled up to meet the fuel demands of the sector.
- The mandate applies to all fuel sold in Union airports<sup>1</sup>, therefore covering all flights including long-haul departing flights.
- The Regulation includes a financial penalty for non-compliance.

## What's good? What's not?

Mandating the use of SAF is essential to reduce aviation's climate impact. Covering all flights within and departing from the bloc is an important distinction from other climate measures adopted to date, such as the ETS, which have only covered flights within the EU (less than 40% of emissions).

---

<sup>1</sup> Where passenger traffic is higher than 1 million passengers or where freight traffic is higher than 100,000 tons

The proposal will also replace existing and planned national SAF mandates, a positive step as many of them are relying on crop-based biofuels. At the same time, it remains possible for EU member states to enact policies to drive a quicker SAF uptake, including State aid, R&D funding and industrial alliances to facilitate cooperation between all stakeholders.

The Commission has also proposed an anti-tankering provision requiring airlines to uplift from each Union airport at least 90% of the jet fuel required to perform flights from each of these airports. This is to prevent airlines avoiding the SAF mandate by purchasing extra fuel outside of the EU. This is a concrete measure to avoid competitive distortion to the disadvantage of EU airlines

The proposal goes some way towards selecting the right types of SAFs. It excludes food and feed crop-based biofuels and instead focuses on advanced biofuels and e-kerosene.

- Advanced biofuels (part A of the RED's Annex IX): include wastes and residues, but also co-products and some primary products. There are very limited feedstocks that have no other uses and that could be used for biofuels without any significant impact on existing markets, on the environment and the climate<sup>2</sup>. So the targets should be low.
- Used cooking oil and animal fats categories 1 and 2 (part B of the RED's Annex IX): they are available in very limited quantities and have a competing use with the road sector. As such, if they are not strictly limited under ReFuelEU, these feedstocks will just shift from road to aviation, and will not create additional GHG savings.
- E-kerosene: is produced from renewable electricity and captured CO<sub>2</sub>. When the renewable electricity is additional and the CO<sub>2</sub> is captured from the atmosphere (Direct Air Capture (DAC)), the fuel has close to zero net CO<sub>2</sub> emissions. Our FAQ on e-kerosene answers some comment questions on this fuel<sup>3</sup>.

The Commission's proposal contains targets out to 2050, all of which mandate greater use of advanced biofuels than e-kerosene. This is an unsustainable approach, as the feedstocks of advanced biofuel are too limited to reach these high targets, while the targets for e-kerosene are far from ambitious.

## How should it be improved?

Aviation urgently needs to reduce its climate impact and ReFuelEU should therefore be more ambitious. This can be achieved by correcting the balance between biofuels and e-kerosene so that we reach 100% SAF in 2050.

Advanced biofuels are limited in availability and many types actually have negative environmental and climate impacts. SAF from Part B feedstocks should be capped at 0.65 Mtoe throughout the ReFuelEU

<sup>3</sup> Transport & Environment (2021). *FAQ: the what and how of e-kerosene*  
<https://www.transportenvironment.org/discover/faq-what-and-how-e-kerosene/>

period, which is equivalent to about 1.2% of aviation fuel demand. Biofuels from part A feedstocks should be mandated based on what is sustainably available, starting at 0.3% in 2025 (0.14 Mtoe)<sup>4</sup> and then 2.5% in 2030 (1.3 Mtoe)<sup>5</sup>. We have calculated the maximum availability of SAFs from part A feedstocks at 5.85 Mtoe, which is equivalent to about 10.3% of fuel demand in 2050.

For e-kerosene, the mandate should start in 2025 with a sub-target of 0.03% (small, but meaningful to provide earlier incentives to invest in production capacity) and increasing it to 2% for 2030. For subsequent years, the numbers should further increase and reach almost 90% in 2050, as detailed in the table in Annex I. Furthermore, a certain share of DAC should be required from the first year of the mandate (2025) and rapidly progress to provide 100% of the CO<sub>2</sub> needed for e-kerosene production.

**T&E recommends that:** ReFuelEU's Annex I features our recommended maximum level for part B feedstocks, a target for part A feedstocks, alongside the already existing overall SAF target and an increased minimum sub-target for e-kerosene (including a mandatory sub-share of DAC CO<sub>2</sub>). T&E's preferred numbers are detailed in Annex I.

## Demand management

European aviation traffic has grown steadily before the Covid-19 pandemic, increasing by 83% between 2005 and 2019 (in Revenue Passenger Kilometers). This trend has made it more challenging to reduce emissions, because the greater the fuel demand, the harder it is to decarbonise. Reducing passenger, and therefore fuel, demand will be key for SAFs to have a larger effect in reducing aviation's climate impact.

The table in Annex II is based on fuel demand until 2050 that does not exceed 50% of 2019 business travel demand and 100% of 2019 leisure travel demand. The smaller fuel needs make it feasible to attain a higher SAF share in 2030, on the road to achieving 100% SAF in 2050. This highlights the need to put in place demand management measures, both in terms of kerosene taxation, proper pricing of emissions and cancelled planned airport expansion. It is also essential that companies commit to reducing corporate travel.

**T&E recommends that:** ReFuelEU targets can be revised upwards in the future (as the targets are based on percentages and not absolute amounts) provided that these demand management measures are put in place. Annex II showcases the positive impact of demand management on the volumes of SAF required to decarbonise aviation.

## Addressing aviation's non-CO<sub>2</sub> effects

Non-CO<sub>2</sub> effects (including persistent contrails as well as nitrogen oxide, water vapour and oxidised sulphur species emissions) count for over two thirds of aviation's total climate impact. Despite the urgency of mitigating these effects, Fit for 55 has failed to include any measures to address them.

However, the ambition of ReFuelEU can be broadened to include addressing these effects. The EASA report on non-CO<sub>2</sub><sup>6</sup> explained that by reducing aromatics in conventional fossil fuels, which can be achieved by a process called hydrotreating, these non-CO<sub>2</sub> effects can be reduced. Presently, there are no regulatory measures in place to reduce the levels of aromatics in these fuels.

An effective measure would be to mandate that producers of fossil jet fuel, which will remain the bulk of jet fuel supply for some time, reduce these aromatic levels. This is technically feasible, and is similar to the sort of mandates which are placed on fuel suppliers for i.e. the road transport sector. It would also bring air quality benefits to areas around airports.

**T&E recommends that:** ReFuelEU features a provision requesting the European Commission to publish a report on optimising kerosene aromatic content to mitigate persistent contrail formation and empowering the Commission to regulate the aromatic content through a delegated act.

## Supporting new aircraft

It is important that ReFuel EU adopts a holistic approach and supports the development of zero-emissions (ZE) aircraft such as hydrogen, electric propulsion in the medium run. As such, fuel suppliers should be encouraged to supply green hydrogen or enter in joint-ventures with zero emission aircraft manufacturers. Such joint ventures should be recognised for compliance under ReFuelEU. Europe is already home to an increasing number of ZE aircraft start-up companies.

It's important that Europe supports such initiatives, which can provide a sustainable growth opportunity for the EU's important aeronautical industry.

**T&E recommends that:** support for such aircraft can be achieved through counting of green hydrogen or green electricity used towards EU targets for such energy sources.

## Annex I: Preferred ReFuelEU targets

in Mtoe and percentage of aviation fuel demand (2.2% compound growth rate)

Year	Total	Part A biofuels	Part B biofuels	e-kerosene
2025	0.81 (1.6%)	0.14 (0.3%)	0.65 (1.3%)	0.016 (0.03%)
2030	3.00 (5.7%)	1.30 (2.5%)	0.65 (1.2%)	1.05 (2.0%)
2035	12.36 (22.6%)	4.50 (8.2%)	0.65 (1.2%)	7.21 (13.2%)
2040	28.91 (51.8%)	5.70 (10.2%)	0.65 (1.2%)	22.56 (40.4%)
2045	43.37 (77.3%)	5.84 (10.4%)	0.65 (1.2%)	36.88 (65.8%)
2050	56.88 (100.0%)	5.85 (10.3%)	0.65 (1.1%)	50.38 (88.6%)

## Annex II: Positive impact of demand management on SAF volumes needed

In Mtoe and percentage of aviation fuel demand (demand management forecast)<sup>7</sup>

Year	Total	Part A biofuels	Part B biofuels	e-kerosene
2025	0.81 (2.0%)	0.14 (0.3%)	0.65 (1.6%)	0.016 (0.04%)
2030	3.00 (7.8%)	1.30 (3.4%)	0.65 (1.7%)	1.05 (2.7%)
2035	9.27 (25.3%)	4.50 (12.3%)	0.65 (1.8%)	4.12 (11.3%)
2040	15.63 (45.1%)	5.70 (16.5%)	0.65 (1.9%)	9.28 (26.8%)
2045	21.68 (66.1%)	5.84 (17.8%)	0.65 (2.0%)	15.19 (46.3%)
2050	31.03 (100.0%)	5.85 (18.9%)	0.65 (2.1%)	24.53 (79.0%)

<sup>7</sup> This forecast assumes that fuel demand until 2050 does not exceed 50% of 2019 business travel demand and 100% of 2019 leisure travel demand
